

OpenTelemetry Plugin

Making Distributed Traces Actionable in Rider

Rider Execution Team

Dynamic Program Analysis Research

Goal

How telemetry analysis can help us build development tools that better adapt to real-world developer workflows?

What is the OpenTelemetry plugin for Rider?

This plugin is designed for observability during local and dev/test development. It's not a debugger or profiler – instead, it lets you correlate runtime behavior (logs, metrics, traces) with your code inside Rider.

It helps you answer questions like:

- What happened right before this error?
- Which services did this endpoint call?
- Why is this request slower today than yesterday?

Which features does it have?

- **Service Map based on OTEL traces**
- **Explain log with AI**
- Views for Logs, Metrics and Traces
- Navigate to log statement in a code
- MCP to access logs, traces, metrics, service map
- Auto Instrumentation

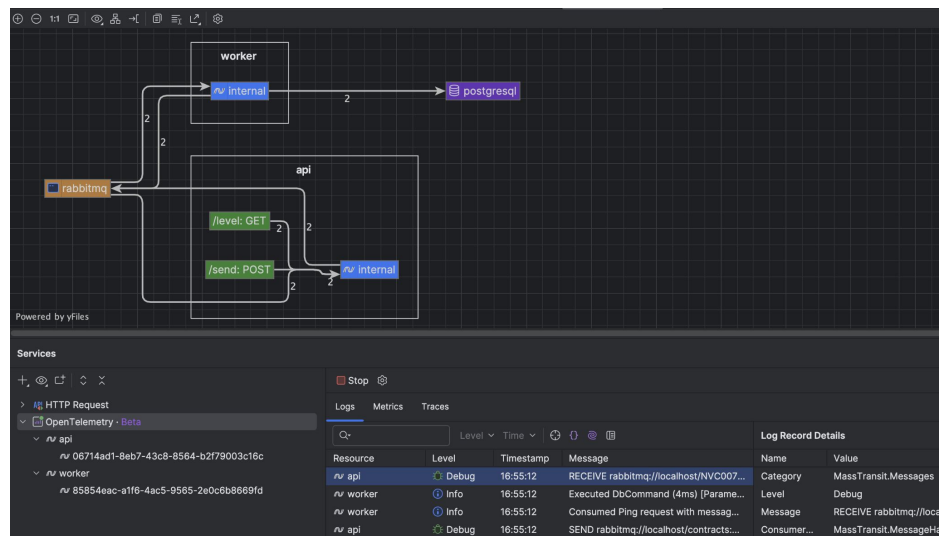

Service Map feature

The plugin can automatically generate architecture diagrams from your execution traces. These aren't static diagrams you have to maintain – they're built directly from how your system actually behaves at runtime, showing services, endpoints, databases, and message queues as they interact in real scenarios.

Developer:

«Potential for very large positive impact on seeing service topology»

Plugin screenshot

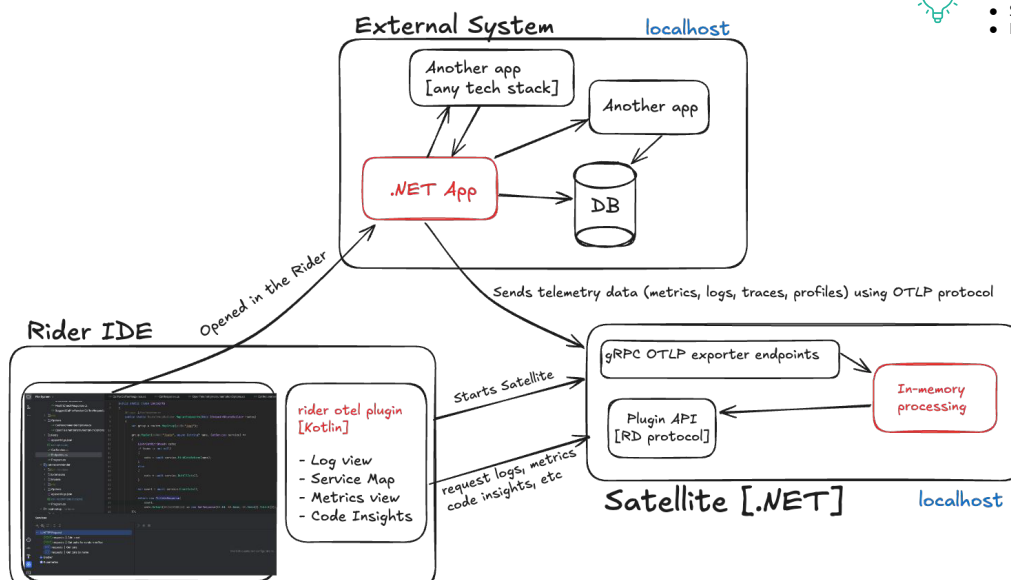

Feedback

- Currently, the plugin has **6% adoption in Rider** (~4.3k active users)
- **19k downloads in a month**
- We also received a **lot of positive reactions** on Twitter
- **Service Map** feature is **the most utilized feature** right after “Start OpenTelemetry” feature

#	Plugin ID	Ratio of Users	Users
12	org.jetbrains.junie	7.3%	5 174
13	com.jetbrains.opentelemetry	6.1%	4 351

How does it work under the hood?

Future work

- Release OpenTelemetry plugin for other IDEs
- Implement support of logs correlated with traces
- Support LLM Calls and agentic services in service map
- Implement inspections for services and agentic services

GIVE IT A TRY
